seriesQ: Does Postgres have a way to discover table names
dynamically? I'm a PostgreSQL DBA. I'm looking to code a
little utility in C that I can use to generate SQL DDL for
tables in the database. I'm not sure if PostgreSQL has a table
meta data system similar to Oracle Database's
'ALL_TABLES'. I'm not looking for a way to find out what
the tables and columns are in a particular schema. I'm looking
for a way to find out which table a certain function returns.
A: Yes, there is. `select table_schema from
information_schema.tables;` If you want to know which table
an function returns, then you'll need to use the function's own
documentation. `select table_name from
information_schema.function_calls where function_schema
= 'public' and name ='my_func';` A: Create a table like
`CREATE TABLE "your_schema"."dynamic_table" ("col_1"
int);` Then run a query like `SELECT * FROM
"your_schema"."dynamic_table";` and the result set should be
a list of all the columns defined in all the tables that
"your_schema" refers to. (It would be a problem if one table
had two or more columns with the same name; presumably
you can code to address that case.) If you need to do the

query via a function, the WITH clause lets you put the table's definition into a local variable. A: No. You can create a temporary table, and look at its definition with something like: `SELECT oid, (SELECT string_to_array('table ', oid::text::integer, "::text[]") AS definition, * FROM pg_class c WHERE c.oid = pg_temp 2d92ce491b`
